The Economic Ripple Effects of COVID-19
...or a Really Large Transitory Shock

Francisco J. Buera[1]   Roberto N. Fattal-Jaef[2]

Hugo Hopenhayn [4]   P. Andrés Neumeyer [3]   Yongseok Shin [1]

January 12, 2021

Motivation

- COVID+non-pharmaceutical interventions (NPIs):

  - ▷ largest (transitory?) aggregate shock since... ▸ Data table
  - ▷ more permanent reshuffling of what we consume and how we produce?

- This paper, relatively agnostic quantitative exploration of:

  - ▷ Ripple effects of a LARGE transitory shock, e.g., lockdown?
  - ▷ Relative role of shocks in the pandemic: lockdown, reallocation, demand?
  Role of
  - ▷ financial frictions
  - ▷ labor market frictions

  - ▷ labor market policies and institutions
  - ▷ size of shock
  - ▷ persistence of shock

2011	91	95
2012	98	99

Roadmap

- Describe model
- Analyze macro and micro implications of:

  1. one-period lockdown shock in baseline model:
     - non-essential firms have zero employment/output/income
     - demand shock $\frac{I_1}{C_1} = 0.93 \frac{I_{ss}}{C_{ss}}$ (US Q2)
     - Firms liable for rental/debt payments
     - wage bill paid by government with future lump-sum taxes

  2. Sensitivity to size & duration of shock

  3. Role of modeling assumptions in persistence of lockdown shock
     - demand shock
     - Firms liable for wage payments
     - employment recall

  4. Added reallocation shock (non-essential/essential)

This Paper

- Heterogeneous Agents model
  - ▷ occupational choices
  - ▷ stochastic entrepreneurial ability

$$z_t = \begin{cases} z_{t-1} & \text{with prob } \psi \\ z \sim \text{Pareto} & \text{otherwise} \end{cases}$$

  - ▷ **credit friction**: collateral constraints, $k_t \leq \lambda a_t$
  - ▷ **labor friction**: matching friction w/ rest unemployment

- Deterministic dynamics following unanticipated shocks:
  - ▷ Lockdown: fraction ϕ of all firms becomes Non-Essential (shut-down).
  - ▷ Demand: low marginal utility first period (equivalent to more patience)
  - ▷ Reallocation shock: firms in non-essential sector redraw their productivity, $\psi_2^{NE} < \psi = 0.97$

- Buera, Fattal-Jaef & Shin (2015)+ (simple version of) Alvarez & Shimer (2011)

Agent's Optimization Problem: Essential

$$v_t(z, a) = max_{a', oc} \left\{ \xi_t \frac{[c_t]^{1-\sigma}}{1-\sigma} + \beta E v_{t+1}[z', a'] \right\}$$

$$c_t + a_{t+1} = max\{w_t, \pi_t(z, a_t; r_t, w_t)\} + (1+r_t)a_t - \tau_t$$

where

$$\pi_t(z, a; r, w) = \max_{k, l} zk^\alpha l^\theta - (r+\delta)k - wl$$

subject to $k \leq \lambda a$

- Full replacement unemployment insurance: w_t
- Unemployment insurance financed with lump-sum taxes over T periods , $\sum_{t=1}^{T} q_t w_t U_t = \sum_{t=1}^{T} q_t \tau_t$

Agent's Optimization Problems: Non-Essential

- **Businesses**

$$v_1^{NE}(z, a) = max_{a'} \left\{ \xi_1 \frac{[c_t]^{1-\sigma}}{1-\sigma} + \beta E v_2 [z', a'] \right\}$$

$$c_1 + a_2 = -(r+\delta) k_{1-} + (1+r_1) a_1 - \tau_1$$

- **Workers**

$$v_1^W(z, a) = max_{a'} \left\{ \xi_1 \frac{[c_t]^{1-\sigma}}{1-\sigma} + \beta E v_2 [z', a'] \right\}$$

$$c_1 + a_2 = w_1 + (1+r_1) a_1 - \tau_1$$

- Non-essential entrepreneurs only pay rental cost, $-(r+\delta) k_{1-}$
  - ▷ employment at will (US) or generous government wage subsidies (Europe)
- non-essential become essential for $t \geq 2$

Labor Market Friction

- M_t unemployed workers matched to the hiring market

$$M_t = \gamma \left(U_t + JD_t \right)$$

- Evolution of Unemployment

$$U_{t+1} = U_t + JD_t - M_t$$
$$= (1 - \gamma) \left(U_t + JD_t \right)$$

- Job Destruction

$$JD_t = \int \left[\max \left\{ l_{t-1} - l_t \left(a, z \right), 0 \right\} \right] dG_t \left(a, l_{t-1}, z \right) + \text{exiting entrep.}$$

- Walrasian Hiring Market Clearing

$$\underbrace{\int_{l_t(a,z)>0} \left[1 + l_t \left(a, z \right) \right] dG_t \left(a, l_{t-1}, z \right)}_{\text{labor demand}} = \underbrace{1 - U_{t+1}}_{\text{labor supply}}$$

Labor Market Friction with Rest Unemployment

- non-essential workers are not reallocated in the first period

- but can be rehired frictionlessly by their previous employers in the second period

  ▷ only by surviving firms

  ▷ if their net-worth constraint does not bind

Labor Market Friction with Rest Unemployment

- M_t unemployed workers matched to the hiring market

$$M_1 = \gamma \left(U_1 + JD_1 - R_2 \right)$$

and

$$R_2 = \psi \int \min \left\{ l_2 \left(a, z \right), l_{1-} \right\} dG_2^{NE} \left(a, l_{1-}, z \right)$$

  ▷ i.e., job destruction by non-essential can be re-hired the following period

- Evolution of Unemployment

$$U_2 = (1 - \gamma)(U_1 + JD_1 - R_2)$$

- Walrasian Hiring Market Clearing

$$\underbrace{\int_{l_2(a,z)>0} \left[1 + l_2 \left(a, z \right) \right] dG_2 \left(a, l_{1-}, z \right)}_{\text{labor demand}} = \underbrace{1 - U_2}_{\text{labor supply}}$$

- Parameter values set to match

    - ▷ distribution and dynamics of U.S. establishments

    - ▷ unemployment rate in U.S. (γ)

    - ▷ external finance to fixed capital in non-corporate sector in U.S. (λ)

        - ► also calibration to external finance in developing countries (not today)

Roadmap

- Describe model
- Analyze macro and micro implications of:
  1. one-period lockdown shock in baseline model:
     - non-essential firms have zero employment/output/income
     - demand shock $\frac{I_1}{C_1} = 0.93 \frac{I_{ss}}{C_{ss}}$ (US Q2)
     - Firms liable for rental/debt payments
     - wage bill paid by government with future lump-sum taxes
  2. Sensitivity to size & duration of shock
  3. Role of modeling assumptions in persistence of lockdown shock
     - demand shock
     - Firms liable for wage payments
     - employment recall
  4. Added reallocation shock (non-essential/essential)

The Lock-Down Shock

- Start from stationary allocation

- Unexpected shock: fraction ϕ of businesses considered Non-Essential

    ▷ magnitude and persistence of ϕ still open question

    ▷ assume $\phi = 0.1$, 1-period shock →emphasize model's propagation
    (Sensitivity to $\phi = 0.3, 0.2$, 2-period shock)

    ▷ shock realized after occupation and factor demand decisions, but before
    production

- labor costs in the first period are not paid by the firm, e.g., wage subsidies
  (Europe), furlough (US)

    ▷ we look at the case in which firms must pay wage bill later

1. Burst of job destruction+matching friction → rise in (rest?) unemployment

2. Imperfect insurance → negative shock to net-worth of affected entrepreneurs

3. Lowered net worth + Financial Frictions →
   ▷ not all unemployed workers are recalled
   ▷ persistent unemployment because of financial and labor market frictions
   ▷ Capital stock and investment are affected
   ▷ Impact on *TFP* (misallocation, operating organization capital)

4. Some expansion of essential firms → misallocation

Lockdown: Aggregate Variables I
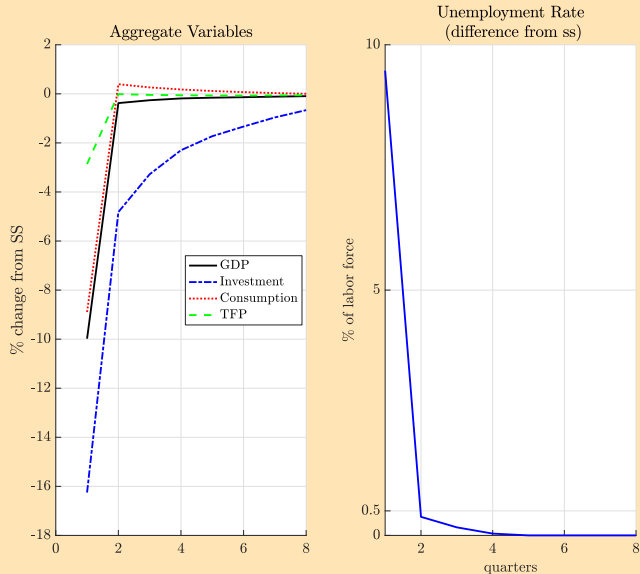

Main features

- Δ GDP = share locked down sector
- Rest U ⇒ quick rebound in employment and GDP
- Fast consumption rebound, overshoot
- Protracted Investment rebound
- $t = 1$ TFP falls due to idle non-essential capital
Prices

Main features

- Change in prices is tiny
- Labor friction limits wage pressure
- ↓ credit demand ⇒ Initial drop in interest rate

Micro Implications I : Employment by Age
Young firms
- less than 5 years old
  ▷ 20% of employment
  ▷ non-essential 2% employment

- more **financially constrained**

- driving force of "persistent" unemployment
 ▷ persistently below trend (20% in $t = 1$)

Young firms
- less than 5 years old
  ▷ 20% of employment
  ▷ non-essential 2% employment

- more **financially constrained**

- driving force of "persistent" unemployment
  ▷ persistently below trend (20% in $t = 1$)

# Micro Implications III: Consumption

Why does C fall?

- Demand shock
- Imperfect insurance hits entrepreneurs in non-essential sector
- Workers have unemployment insurance

Roadmap

- Describe model
- Analyze macro and micro implications of:
  1. one-period lockdown shock in baseline model:
     - non-essential firms have zero employment/output/income
     - demand shock $\frac{I_1}{C_1} = 0.93 \frac{I_{ss}}{C_{ss}}$ (US Q2)
     - Firms liable for rental/debt payments
     - wage bill paid by government with future lump-sum taxes
  2. Sensitivity to size & duration of shock
  3. Role of modeling assumptions in persistence of lockdown shock
     - demand shock
     - Firms liable for wage payments
     - employment recall
  4. Added reallocation shock (non-essential/essential)

Sensitivity to Size: Macro Implications

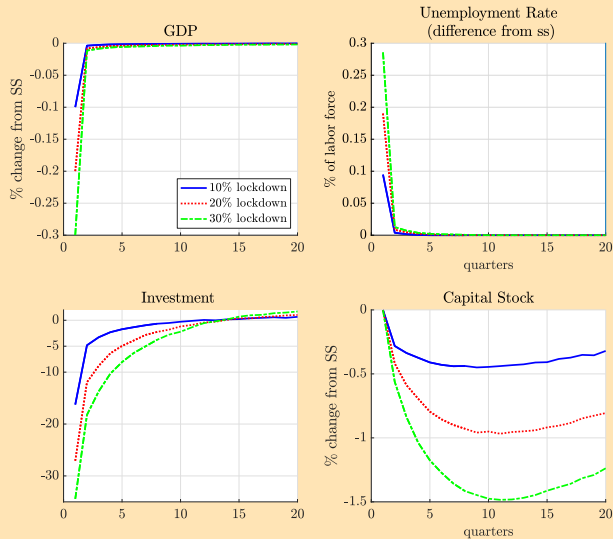

Larger shock?

- Effect ≈ linear in size
- More persistence through capital
- Larger deficits:

Share of yearly GDP

10%	20%	30%
0.013	0.027	0.04

Sensitivity to Size: Macro Implications

Larger shock?

- Effect ≈ linear in size
- More persistence through capital
- Larger deficits

| Share of yearly GDP		
10%	20%	30%
0.013	0.027	0.04
Larger shock?

- Similar micro implications
- Size affect fraction NE
- NE slightly better off, better factor prices

Longer lockdown?

- Disproportionally more protracted recovery
- More persistence through unemployment & capital

Longer lockdown?

- Disproportionally more protracted recovery
- More persistence through unemployment & capital

Employment Young / Employment Old
Legend:
- Essential, 1 period
- Essential, 2 period
- Non Essential, 1 period
- Non Essential, 2 period
- steady state

Longer shock?

- Young firms even more financially constrained
- Undermining recall of rest unemployed

Roadmap

- Describe model
- Analyze macro and micro implications of:

  1. one-period lockdown shock in baseline model:
     - non-essential firms have zero employment/output/income
     - demand shock $\frac{I_1}{C_1} = 0.93 \frac{I_{ss}}{C_{ss}}$ (US Q2)
     - Firms liable for rental/debt payments
     - wage bill paid by government with future lump-sum taxes

  2. Sensitivity to size & duration of shock

  3. Role of modeling assumptions in persistence of lockdown shock
     - demand shock
     - Firms liable for wage payments
     - employment recall

  4. Added reallocation shock (non-essential/essential)

Unpacking the ripples: shocks, policies, mechanisms
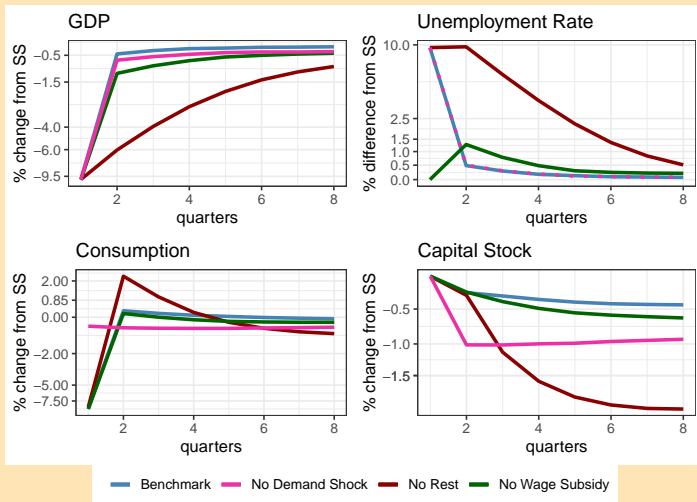

1. Start with 10% lockdown with demand shock
2. Eliminate demand shock
3. No rest unemployment: delays recovery
4. Add firms pay lockdown wages instead of UI: delays recovery through balance sheet effect.

Roadmap

- Describe model
- Analyze macro and micro implications of:
  1. one-period lockdown shock in baseline model:
     - non-essential firms have zero employment/output/income
     - demand shock $\frac{I_1}{C_1} = 0.93 \frac{I_{ss}}{C_{ss}}$ (US Q2)
     - Firms liable for rental/debt payments
     - wage bill paid by government with future lump-sum taxes

  2. Sensitivity to size & duration of shock

  3. Role of modeling assumptions in persistence of lockdown shock
     - demand shock
     - Firms liable for wage payments
     - employment recall

  4. Added reallocation shock (non-essential/essential)

- Start from stationary allocation ▸ tree

- At $t = 1$, 10% of firms are locked down (non-essential)
- At $t = 2$ an extra 30% of these firms redraw productivity z

  ▷ It captures more permanent reshuffling of what/how we consume/produce

- in a neoclassical world there are no aggregate consequences
- recovery slowed down by financial and labor frictions
- Persistent recession.
- Two frictions at work
  ▷ Redraw of productivity with financial constraint generate distortions due to mismatches between entrepreneurial productivity and wealth.
  ▷ Entrepreneurs and workers in exiting firms are not reallocated immediately due to labor market friction (no rest unemployment in this case)
- Consumption rebounds fast
- The financial constraint is reducing investment and aggregate demand so that interest rates fall
- Price changes are tiny

Summary of Results and lessons

1. In most cases there is a fast aggregate recovery from unprecedented contraction in GDP due to lockdowns,
   ▷ which is possible due to wage support/flexible employment & rest unemployment,
   ▷ but persistent effects remain after initial recovery due to balance sheet effects in young firms.

2. Inflexible employment with weak support policies or prolonged lockdowns have large ripple effects.

3. Reallocation due to a new structure of demand and "entrepreneurial switching" has persistent effects

- Distribution of welfare costs
  - ▷ Who gain from wage subsidies, milder ripple effects?

- Small open economy and current account dynamics

- Differentiate essential and non-essential goods.
